

## Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

Read more about Early Journal Content at <http://about.jstor.org/participate-jstor/individuals/early-journal-content>.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact [support@jstor.org](mailto:support@jstor.org).

Society, held at Philadelphia, for promoting Useful Knowledge, three-fourths of the funds belonging to the Institute, for four years, without interest; and shall loan to the Historical Society of Pennsylvania one-fourth of the remainder of such funds, for four years, without interest; the said loans to be secured by bond and warrant of attorney.

Mr. Sill's letter mentioned that the amount which might be expected by the Society, will be from \$700 to \$900.

On motion of Dr. Patterson—*Resolved*, That the loan offered by the Athenian Institute be accepted by the Society, and that the President and Treasurer be instructed to affix the corporate seal to the stipulated securities.

*Resolved*, That the Secretary be instructed to convey to the Counsellors of the Athenian Institute, the acknowledgments of the Society for the aid so liberally tendered.

On motion of Mr. Fraley, the Society proceeded to consider the alteration of the By-laws, proposed at the meeting of the 15th instant.

### *Stated Meeting, June 19.*

Present, twenty-six members.

Dr. PATTERSON, Vice-President, in the Chair.

Letters were announced and read:—

From the Linnean Society of London, dated April 2d, 1846, acknowledging the receipt of the Transactions of the Society, Vol. IX. Part 2d, and of the Proceedings, Nos. 32 and 33:—

From the Royal Institute of Sciences, Belles Lettres and Arts, of the Low Countries, dated Amsterdam, Jan. 23, 1846, on transmitting a part of the Transactions of the Institution:—

From the Historical Society of New York, dated New York, May 22d, 1846, on transmitting copies of a circular in reference to proposed changes in the tariff, as affecting the interests of literary institutions:—

From the Local Committee of the Association of American

Geologists and Naturalists, dated New York, June 5th, 1846, transmitting copies of circulars of the Association:—

From Signor Zantedeschi, dated Venice, Aug. 14, 1845, on transmitting a donation to the Society:—

From Von Hammer Purgstall, dated Vienna, Feb. 25, 1846, on transmitting a donation to the Society:—

From the friends of the late Prof. Bessel, dated Königsberg, March 21, 1846, announcing his death:—

From the family of the late Mr. Pickering, of Boston, dated Boston, June 9th, 1846, on returning a MS. of Mr. S. S. Haldeman's to the Secretary:—and,

From Mr. Henry M'Ilvaine, dated Philadelphia, June 11, 1846, asking for two Mexican silver drinking cups, and a cestus, deposited many years ago by Mr. Joseph E. Bloomfield.

On motion of Mr. Ord, the Curators were authorized to return the articles deposited in the Cabinet to Mr. M'Ilvaine, as the representative of Mr. Bloomfield.

The following donations were announced:—

The presiding officer announced the death of Mr. Redmond Conyngham, of Paradise, County of Lancaster, a member of this Society, who died on the 16th inst., at the age of 64. On motion of Mr. Ord, Bishop Potter was requested to prepare an obituary notice of the deceased.

A portion of a communication from Miss Reynolds to the Rev. Archibald Alexander, of Princeton, detailing a condition

of two distinct states of consciousness, of which she described herself as the subject, was read.

On motion, the communication was referred to a Committee, consisting of Dr. Hays, Dr. Coates, and Dr. Bell.

Prof. Henry presented a paper from Capt. Stockton, U. S. Navy, entitled, "On some of the Results of a Series of Experiments, relative to different parts of Gunnery," which was referred to a Committee, consisting of Prof. Henry, Prof. Frazer, and Dr. Patterson.

A letter from S. D. Ingham to Dr. Patterson was read, detailing cases in which the telegraphic wires were struck by lightning, and asking the attention of the Society to some interesting questions connected with the mode in which the wires may be affected by electricity.

*New Hope, 5th June, 1846.*

My dear Sir,—I have recently observed a fact, which it may be interesting to investigate. During a heavy *thunder shower*, as we say, on the 25th ult., several poles which support the wires of the new telegraph were stricken by the lightning. In one case, *four* in succession; and in another, *two*; this happened within three-quarters of a mile of my house. I hear, also, that many others between this and Doylestown are also marked with the lightning. The wires do not appear to be affected. The first appearance of effect on the poles is where the tenon enters the cross-bar on the top. A knowledge of the modus in which the electric charge passes along the wires, might aid in determining whether the telegraph, as constructed, will be a protection, or increase the danger from lightning. Why does the electricity leave the copper wire, and pass off into wood, without affecting the wire? We want to know by experiment, from those who are skilled in these matters, and are provided with apparatus, whether our security is increased or lessened by the construction of the telegraphic machinery. The poles are set along the road upon which persons are constantly passing with horses, carriages, &c., which, for aught we know, may be as likely to attract the electric matter from the surcharge as a wooden pole; and if such be the fact, what is the best remedy? Will frequent conductors on the poles be a sufficient security?

This subject deserves consideration in another point of view; for if it should happen that any person should be killed by lightning on the

road near the conducting wires, the telegraph will very probably soon be demolished, and might not easily be again renewed.

Will you have the goodness to present this subject to the consideration of the Philosophical Society, and invite the attention of the members to it; and accept the assurance of the very great respect of

Your most obedient,

Dr. ROBT. PATTERSON.

S. D. INGHAM.

Professor Henry, to whom the foregoing letter was referred, made the following report:—

The action of the electricity of the atmosphere on the wires of the electrical telegraph, is at the present time a subject of much importance, both on account of its practical bearing, and the number of purely scientific questions which it involves. I have accordingly given due attention to the letter referred to me, and have succeeded in collecting a number of facts in reference to the action in question. Some of these are from the observations of different persons along the principal lines, and others from my own investigations during a thunder storm on the 19th of June, when I was so fortunate as to be present in the office of the telegraph in Philadelphia, while a series of very interesting electrical phenomena was exhibited. In connexion with the facts derived from these sources, I must ask the indulgence of the Society in frequently referring, in the course of this communication, to the results of my previous investigations in dynamic electricity, accounts of which are to be found in the *Proceedings and Transactions* of this Institution.

From all the information on the subject of the action of the electricity of the atmosphere on the wires of the telegraph, it is evident that effects are produced in several different ways.

1. The wires of the telegraph are liable to be struck by a direct discharge of lightning from the clouds, and several cases of this kind have been noticed during the present season. About the 20th of May the lightning struck the elevated part of the wire, which is supported on a high mast at the place where the telegraph crosses the Hackensack river. The fluid passed along the wire each way from the point which received the discharge, for several miles, striking off at irregular intervals down the supporting poles. At each place where the discharge to a pole took place, a number of sharp explosions were heard in succession, resembling the rapid reports of several rifles. During another storm, the wire was struck in two places in Pennsylv-

vania, on the route between Philadelphia and New York; at one of these places twelve poles were struck, and at the other eight. In the latter case, the remarkable fact was observed, that every other pole escaped the discharge; and the same phenomenon was observed, though in a less marked degree, near the Hackensack river. In some instances the lightning has been seen coursing along the wire in a stream of light; and in another case it is described as exploding from the wire at certain points, though there were no bodies in the vicinity to attract it from the conductor.

In discussing these, and other facts to be mentioned hereafter, we shall, for convenience, adopt the principles and language of the theory which refers the phenomena of electricity to the action of a fluid, of which the particles repel each other, and are attracted by the particles of other matter. Although it cannot be affirmed that this theory is an actual representation of the cause of the phenomena, as they are produced in nature, yet it may be asserted that it is, in the present state of science, an accurate mode of expressing the laws of electrical action, so far as they have been made out; and that though there are a number of phenomena which have not as yet been referred to this theory, there are none which are proved to be directly at variance with it.

That the wires of the telegraph should be frequently struck by a direct discharge of lightning, is not surprising, when we consider the great length of the conductor, and, consequently, the many points along the surface of the earth through which it must pass, peculiarly liable to receive the discharge from the heavens. Also, from the great length of the conductor, the more readily must the repulsive action of the free electricity of the cloud drive the natural electricity of the conductor to the farther end of the line, thus rendering more intense the negative condition of the nearer part of the wire, and, consequently, increasing the attraction of the metal for the free electricity of the cloud. It is not, however, probable that the attraction, whatever may be its intensity, of so small a quantity of matter as that of the wire of the telegraph, can of itself produce an electrical discharge from the heavens: although, if the discharge were started by some other cause, such as the attraction of a large mass of conducting matter in the vicinity, the attraction of the wire might be sufficient to change the direction of the descending bolt, and draw it in part or in whole to itself. It should also be recollected, that on account of the perfect conduction, a discharge on any part of the wire

must affect every other part of the connected line, although it may be hundreds of miles in length.

That the wire should give off a discharge to a number of poles in succession, is a fact I should have expected, from my previous researches on the lateral discharge of a conductor transmitting a current of free electricity. In a paper on this subject, presented to the British Association in 1837, I showed that when electricity strikes a conductor explosively, it tends to give off sparks to all bodies in the vicinity, however intimately the conductor may be connected with the earth. In an experiment in which sparks from a small machine were thrown on the upper part of a lightning rod, erected in accordance with the formula given by the French Institute, corresponding sparks could be drawn from every part of the rod, even from that near the ground. In a communication since made to this Society, I have succeeded in referring this phenomenon to the fact, that during the transmission of a quantity of electricity along a rod, the surface of the conductor is charged in succession, as it were, by a wave of the fluid, which, when it arrives opposite a given point, tends to give off a spark to a neighbouring body, for the same reason that the charged conductor of the machine gives off a spark under the same circumstances.

It might at first be supposed that the redundant electricity of the conductor would exhaust itself in giving off the first spark, and that a second discharge could not take place; but it should be observed, that the wave of free electricity, in its passage, is constantly attracted to the wire by the portion of the uncharged conductor which immediately precedes its position at any time; and hence but a part of the whole redundant electricity is given off at one place; the velocity of transmission of the wave as it passes the neighbouring body, and its attraction for the wire, preventing a full discharge at any one place. The intensity of the successive explosions is explained by referring to the fact, that the discharge from the clouds does not generally consist of a single wave of electricity, but of a number of discharges along the same path in rapid succession, or of a continuous discharge which has an appreciable duration; and hence the wire of the telegraph is capable of transmitting an immense quantity of the fluid thus distributed over a great length of the conductor.

The remarkable facts of the explosions of the electricity into the air, and of the poles being struck in interrupted succession, find a plausible explanation in another electrical principle which I have established, namely, in all cases of the disturbance of the equi-

brium of the electrical plenum, which we must suppose to exist throughout all terrestrial space, the state of rest is attained by a series of diminishing oscillations. Thus, in the discharge of a Leyden jar, I have shown that the phenomena exhibited cannot be explained by merely supposing the transfer of a quantity of fluid from the inner to the outer side of the jar; but in addition to this we are obliged to admit the existence of several waves, backwards and forwards, until the equilibrium is attained. In the case of the discharge from the cloud, a wave of the natural electricity of the metal is repelled each way from the point on which the discharge falls, to either end of the wire, is then reflected, and in its reverse passage meets in succession the several waves which make up the discharge from the cloud. These waves will therefore interfere at certain points along the wire, producing, for a moment, waves of double magnitude, and will thus enhance the tendency of the fluid at these points to fly from the conductor. I do not say that the effects observed were actually produced in this way; I merely wish to convey the idea that known principles of electrical action might, under certain circumstances, lead us to anticipate such results.

2. The state of the wire may be disturbed by the conduction of a current of electricity from one portion of space to another, without the presence of a thunder cloud; and this will happen in case of a long line, when the electrical condition of the atmosphere which surrounds the wire at one place is different from that at another. Now it is well known that a mere difference in elevation is attended with a change in the electrical state of the atmosphere. A conductor, elevated by means of a kite, gives sparks of positive electricity in a perfectly clear day; hence, if the line of the telegraph passes over an elevated mountain ridge, there will be continually, during clear weather, a current from the more elevated to the lower points of the conductor.

A current may also be produced in a long level line, by the precipitation of vapour in the form of fog at one end, while the air remains clear at the other; or by the existence of a storm of rain or snow at any point along the line, while the other parts of the wire are not subjected to the same influence.

Currents of sufficient power to set in motion the marking machine of the telegraph have been observed, which must have been produced by some of these causes. In one case the machine spontaneously began to operate without the aid of the battery, while a snow storm was falling at one end of the line, and clear weather existed at the other.

On another occasion, a continued stream of electricity was observed to pass between two points at a break in the wire, presenting the appearance of a gas-light almost extinguished. A constant effect of this kind indicates a constant accession of electricity at one part of the wire, and a constant discharge at the other.

3. The natural electricity of the wire of the telegraph is liable to be disturbed by the ordinary electrical induction of a distant cloud. Suppose a thunder-cloud, driven by the wind in such a direction as to cross one end of the line of the telegraph at the elevation, say of a mile; during the whole time of the approach of the cloud to the point of its path directly above the wire, the repulsion of the redundant electricity with which it is charged would constantly drive more and more of the natural electricity of the wire to the farther end of the line, and would thus give rise to a current. When the cloud arrived at the point nearest to the wire, the current would cease for a moment; and as the repulsion gradually diminished by the receding of the cloud, the natural electricity of the wire would gradually return to its normal state, giving rise to a current in an opposite direction. If the cloud were driven by the wind parallel to the line of the telegraph, a current would be produced towards each end of the wire, and these would constantly vary in intensity with the different positions of the cloud. Although currents produced in this way may be too feeble to set in motion the marking apparatus, yet they may have sufficient power to influence the action of the current of the battery so as to interfere with the perfect operation of the machine.

4. Powerful electrical currents are produced in the wires of the telegraph by every flash of lightning which takes place within many miles of the line, by the action of dynamic induction; which differs from the action last described, in being the result of the influence of electricity *in motion* on the natural electricity of the conductor. The effect of this induction, which is the most fruitful source of disturbance, will be best illustrated by an account of some experiments of my own, presented to the Society in 1843. A copper wire was suspended by silk strings around the ceiling of an upper room, so as to form a parallelogram of about sixty feet by thirty on the sides; and in the cellar of the same building, immediately below, another parallelogram of the same dimensions was placed. When a spark from an electrical machine was transmitted through the upper parallelogram, an induced current was developed in the lower one, sufficiently powerful to magnetize needles, although two floors intervened, and the conductors were separated to the distance of thirty feet. In this

experiment no electricity passed through the floors from one conductor to the other; the effect was entirely due to the repulsive action of the electricity in motion in the upper wire on the natural electricity of the lower. In another experiment, two wires, about 400 feet long, were stretched parallel to each other between two buildings; a spark of electricity sent through one produced a current in the other, though the two were separated to the distance of 300 feet; and from all the experiments, it was concluded that the distance might be indefinitely increased, provided the wires were lengthened in a corresponding ratio.

That the same effect is produced by the repulsive action of the electrical discharge in the heavens, is shown by the following modification of the foregoing arrangement. One of the wires was removed, and the other so lengthened at one end, as to pass into my study, and thence through a cellar window into an adjacent well. With every flash of lightning which took place in the heavens within at least a circle of twenty miles around Princeton, needles were magnetized in the study by the induced current developed in the wire. The same effect was produced by soldering a wire to the metallic roof of the house, and passing it down into the well; at every flash of lightning a series of currents in alternate directions was produced in the wire.

I was also led, from these results, to infer that induced currents must traverse the line of a rail-road, and this I found to be the case. Sparks were seen at the breaks in the continuity of the rail, with every flash of a distant thunder cloud.

Similar effects, but in a greater degree, must be produced on the wire of the telegraph, by every discharge in the heavens; and the phenomena which I witnessed on the 19th of June in the telegraph office in Philadelphia, were, I am sure, of this kind. In the midst of the hurry of the transmission of the congressional intelligence from Washington to Philadelphia, and thence to New York, the apparatus began to work irregularly. The operator at each end of the line announced at the same time a storm at Washington, and another at Jersey City. The portion of the circuit of the telegraph which entered the building, and was connected with one pole of the galvanic battery, happened to pass within the distance of less than an inch of the wire which served to form the connexion of the other pole with the earth. Across this space, at an interval of every few minutes, a series of sparks in rapid succession was observed to pass; and when one of the storms arrived so near Philadelphia that the lightning could be seen, each series of sparks was found to be simultaneous

with a flash in the heavens. Now we cannot suppose, for a moment, that the wire was actually struck at the time each flash took place; and indeed it was observed that the sparks were produced when the cloud and flash were at the distance of several miles to the east of the line of the wire. The inevitable conclusion is, that all the exhibition of electrical phenomena witnessed during the afternoon, was purely the effects of induction, or the mere disturbance of the natural electricity of the wire at a distance, without any transfer of the fluid from the cloud to the apparatus.

The discharge between the two portions of the wire continued for more than an hour, when the effect became so powerful, that the superintendent, alarmed for the safety of the building, connected the long wire with the city gas pipes, and thus transmitted the current silently to the ground. I was surprised at the quantity and intensity of the current; it is well known, that to affect a common galvanometer with ordinary electricity, requires the discharge of a large battery; but such was the quantity of the induced current exhibited on this occasion, that the needle of an ordinary vertical galvanometer, with a short wire, and apparently of little sensibility, was moved several degrees.

The pungency of the spark was also, as might have been expected, very great. When a small break was made in the circuit, and the parts joined by the forefinger and thumb, the discharge transmitted through the hand affected the whole arm up to the shoulder. I was informed by the superintendent, that on another occasion a spark passed over the surface of the spool of wire, surrounding the legs of the horse-shoe magnet at right angles to the spires; and such was its intensity and quantity, that all the wires across which it passed were melted at points in the same straight line as if they had been cut in two by a sharp knife.

---

The effects of the powerful discharges from the clouds may be prevented, in a great degree, by erecting at intervals along the line, and aside of the supporting poles, a metallic wire, connected with the earth at the lower end, and terminating above at the distance of about half an inch from the wire of the telegraph. By this arrangement the insulation of the conductor will not be interfered with, while the greater portion of the charge will be drawn off. I think this precaution of great importance at places where the line crosses a river, and is supported on high poles. Also in the vicinity of the office of

the telegraph, where a discharge, falling on the wire near the station, might send a current into the house of sufficient quantity to produce serious accidents. The fate of Professor Richman, of St. Petersburg, should be recollected, who was killed, by a flash from a small wire, which entered his house from an elevated pole, while he was experimenting on atmospheric electricity.

The danger, however, which has been apprehended from the electricity leaving the wire and discharging itself into a person on the road, is, I think, very small; electricity, of sufficient intensity to strike a person at the distance of eight or ten feet from the wire, would, in preference, be conducted down the nearest pole. It will, however, in all cases, be most prudent to keep at a proper distance from the wire during the existence of a thunder storm in the neighbourhood.

It may be mentioned as an interesting fact, derived from two independent sources of information, that large numbers of small birds have been seen suspended by the claws from the wire of the telegraph. They had, in all probability, been instantaneously killed, either by a direct discharge, or an induced current from a distant cloud, while they were resting on the wire.

Though accidents to the operators, from the direct discharge, may be prevented by the method before mentioned, yet the effect on the machine cannot be entirely obviated; the residual current which escapes the discharge along the perpendicular wires, must neutralize, for a moment, the current of the battery, and produce irregularity of action in the apparatus.

The direct discharge from the cloud on the wire is, comparatively, not a frequent occurrence, while the dynamic inductive influence must be a source of constant disturbance during the season of thunder storms; and no other method presents itself to my mind at this time for obviating the effect, but that of increasing the size of the battery, and diminishing the sensibility of the magnet, so that, at least, the smaller induced currents may not be felt by the machine. It must be recollected, that the inductive influence takes place at a distance through all bodies, conductors and non-conductors; and hence no coating that can be put upon the wire will prevent the formation of induced currents.

I think it not improbable, since the earth has been made to act the part of the return conductor, that some means will be discovered for insulating the single wire beneath the surface of the earth; the difficulty in effecting this is by no means as great as that of insulating

two wires, and preventing the current striking across from one to the other. A wire, buried in the earth, would be protected, in most cases, from the effect of a direct discharge; but the inductive influence would still be exerted, though perhaps in a less degree.

The wires of the telegraph are too small and too few in number to affect, as some have supposed, the electrical condition of the atmosphere, by equalizing the quantity of the fluid in different places, and thus producing a less changeable state of the weather. The feeble currents of electricity which must be constantly passing along the wires of a long line, may, however, with proper study, be the means of discovering many interesting facts relative to the electrical state of the air over different regions.

A communication was read from Prof. Locke, of Cincinnati, detailing certain phenomena of terrestrial magnetism, as observed in the trap rock of the Brandywine, which exhibited manifest polarity.

Prof. Frazer stated that some of the trap rock of the Brandywine contained magnetic pyrites; and if the rock alluded to by Prof. Locke contained pyrites, it might account for the phenomena.

Mr. Haldeman made the following remarks on the Phonology of the Wyandots.

Missionaries and others have asserted that the peculiarities of this language are such that it cannot be reduced to writing. A tolerably thorough examination of it, with the assistance of Mr. J. E. Armstrong, a native, have shown that this is not the fact. To a person unaccustomed to rigid analysis of the sounds capable of being produced by the organs of speech, it would be found much more difficult to appreciate the peculiarities of the Cherokee.

The Wyandot alphabet is as follows:—1. i (in *field*), 2. 1 (*fit*), 3. e (*where*), 4. ε (*met*), 5. ʒ (*man*, nasal), 6. a (*far*), 7. u (*flaw*, n òt), 8. q (*moan*, no, nasal), 9. o (*word*, n ùt), 10. u (*rule*, fùll), 11. w (English in *we*), 12. m, 13. n, 14. d, 15''. t, 15'. t, 16. ʀ (the smooth English sound, never vibrant), 17. j (*azure*, French j), 18. s (*hiss*), 19. r (*ship*, French *ch*), 20. j (*year*, German *jahr*, Italian *jeri*), 21. g (*gui* in *get*), 22''. k, 22'. k, 23. x (Greek, German *ich*), 24. h (English and German initial in *held*), 25. > (close of the glottis).

The series of vowels is very full, amounting to the five primaries

and five of the secondaries. Several of them are subject to nasality, and two of them,  $\alpha$  in *man* (French *vin*), and  $o$  in *moan* (French *món*), present the peculiarity of being almost always nasalized; the  $o$ , probably, is never natural.

The labial consonants, except *Mi*, and the English *Wi*, are wanting. The 20th letter is frequently nasalized; and when it follows *N* as a nasal, the two become identical with the Spanish *ñ*, which is not an uncommon sound. The German combination *ts* is also somewhat common.

Besides the ordinary *gui* and *ki*, there is a *hard ki*, which has every quality of *gui*, except vocality, as in  $\dot{\alpha}l l k^{\epsilon} s i$ , *Allegeny*. This is heard in other Indian languages, and also in German. The *ti* more rarely assumes the same character, as in  $t u \dot{x} \dot{\epsilon} >$ , an *axe*.

The *hi* (No. 24), presents the peculiarity of being heard with its usual force after a vowel, or as a final; and it is frequently nasalized. Nasal syllables of several letters sometimes occur, as  $h \dot{o} t \dot{\alpha} >$  (the *ear*),  $a w n d \epsilon r r \dot{x} h \dot{a} w$  (for *ever*). The final *hi*, after the close of the glottis, is merely the breath which follows the subsequent opening of the passage, and should properly be represented by the Greek *spiritus asper* (').

The Wyandot numerals, from *one* to *ten*, are as follows. The accented syllable and short vowels should be marked; the former with an accentual, the latter with a dot above.

1.  $s k \dot{o} t$ . 2.  $t \epsilon n d \dot{i}$ . 3.  $r \dot{\epsilon} h k$ . 4.  $n d \dot{a} \chi k$ . 5.  $\dot{u} w l j$ . 6.  $u w a j \dot{u}$ . 7.  $t s \dot{u} t \dot{a} r' \dot{\epsilon} > h$ . 8.  $t \dot{\epsilon} r' \dot{\epsilon} > h$ . 9.  $t r \dot{o} > h$ . 10.  $s \dot{\epsilon} h$ .

Dr. Hays stated that Dr. Warren, of Boston, had given him some information in regard to recently discovered mastodons in New York and New Jersey. One of the skeletons is at Harvard College.

A complete skeleton has been disinterred at Newburgh. It has been purchased by Dr. Warren, and put together by him. It is a *tetracaulodon*.

Dr. Hays pointed out some marked differences between this and the skeletons of the mastodon, which he had examined.

It was moved, by Prof. Frazer, that the letter read this evening from the Historical Society of New York, be referred to a Committee, with power to take order. Mr. Kane, Dr. Ludlow, and Prof. Hare, were appointed the Committee.
